DOMESTIC ABUSE IN LATER LIFE

Abusers

What do perpetrators of domestic abuse in later life have in common? To end elder domestic violence, abusers must stop hurting their victims. To begin this process of determining whether criminal justice, social service, other approaches or a combination is most effective in changing abusers’ behavior, research identifying common traits of abusers can be a starting point. This paper will examine the research that provides information, including gender, about abusers.

This series of papers defines domestic abuse in later life as male and female victims, age 50 and older, abused by someone in a trusted, ongoing relationship like a spouse/partner, family member, or caregiver. The victims lived primarily in the community, not institutions (e.g., nursing homes). Studies from the United States and Canada were included.

ARTICLES REVIEWED

Twenty-one articles published between 1988 and 2000 were reviewed for this article.

| Brownell, et al | 401 cases of abuse of elders 60+ (with 404 identified abusers) known to Elderly Crime Victims Resource Center in New York City; subanalysis done of 218 abusers for whom mental health status was reported | • 56% of abusers male; 44% female (86)  
• 74% of abusers suffered from impairment (substance abuse, mental illness, mental illness/chemical addiction, or dementia). (86)  
• Of the 161 abusers who were impaired, 82 were alcohol/drug abusers; 42 were mentally ill; 27 were both; 10 had dementia. (86)  
• Impaired abusers were more likely to live with victims, be unemployed and have a history of encounters with the criminal justice system. (81) |
| Crichton et al  | 50 Canadians age 60+ abused by adult child; 50 abused by spouse, from Elder Abuse Resource Center in Winnipeg | • Of 50 adult child cases, 34 perpetrators were sons, 19 daughters. (122)  
• Of 50 spouse cases, 43 perpetrators were husbands, 7 wives. (122) |
| Lithwick and Beaulieu | 128 cases of mistreatment of adults aged 60+ brought to the attention of community service agencies in Quebec | • 65% of the perpetrators were men. (101) |
| Anetzberger      | 29 Cleveland APS cases from 1987 to 1995                                     | • “The perpetrator of psychological neglect [3 cases] was always a woman (wife or niece).” (146)  
• “The perpetrator of psychological abuse [26 cases] was slightly more likely (57.1%) to be a man (son, husband, ex-husband, or male companion).” (146) |
| Cohen et al      | 137 spousal/consortial homicide-suicides from 7 Florida counties between 1988 – 1994. 48 involving perpetrators 55+ were compared to 89 | • All older perpetrators were men; 2 younger perpetrators were women. (392)  
• 29% of older perpetrators were depressed and 18.7% had talked of suicide, but only one tested positive for antidepressants at autopsy. (393) |

abusing caregivers. (217)

• “Nearly two-thirds (60.3%) of the abusers had undergone a recent change in their family relationships and two-fifths (41.4%) in living arrangements prior to the onset of abuse or neglect compared to 15.0% and 0.0%, respectively, for the caregivers in the non-abuse situations.” (218)

• “…it appears that both abused elders and the abusers experience emotional problems which contribute to interpersonal difficulties in their relationship.” (223)

Pillemer and Finkelhor 1989
Random sample of 2020 community dwelling people aged 65+ in Boston, Massachusetts; 63 cases of elder abuse found
Physical assault, psychological abuse, and neglect

• The abusers had a very high incidence of socioemotional maladjustment such as having been arrested, hospitalized for psychiatric condition, or involved in other violent behavior. (183 – 184)

• Abusers were likely to be dependent on victim for financial assistance, household repairs, transportation, and housing. (184)

Pillemer and Finkelhor 1988
Random sample of 2020 community dwelling people aged 65+ in Boston, Massachusetts; 63 cases of elder abuse found
Physical assault, psychological abuse, and neglect

• 43% of the physical violence cases were of wife assaulting husband, and 17% were of husband assaulting wife. (54)

GENERALIZED FINDINGS

A number of the studies found that a significant number of abusers suffer some form of impairment (Brownell, 1999; Cohen, 1998; Reis, 1998 and 1997; Seaver, 1996; Greenberg, 1990; Lachs, 1997b; Godkin, 1989; Pillemer, 1989). These impairments included substance abuse, mental illness and depression, or cognitive impairments.

Research also indicated that the abusers tended to be dependent on their victims. This goes against the prevalent notion that elder abuse is primarily caused when frail, elderly are dependent on others for their care. Often this dependence is seen to cause stress as care needs increase and the care provider “snaps” and become abusive. However, a number of studies found that the abuser often depends on the victim for housing, transportation and sometimes care.
Financial dependency of adult children also seems to be a key factor (Reis, 1998; Wolf, 1997; Seaver, 1996; Pillemer, 1989). Some research also suggests that abusers have problems with relationships, may be more isolated and lack social supports (Reis, 1998 and 1997; Godkin, 1989). Brown (1989) suggests that abusers with personal problems may be more physically abusive. Perpetrators may minimize or deny their abusive behavior (Griffin, 1994).

Most studies found the majority of perpetrators to be male (Brownell, 1999; Crichton, 1999; Lithwick, 1999; NEAIS, 1998). Sexual abusers were almost exclusively male (Teaster, 2000; Ramsey-Klawson, 1991). Of the cases reviewed, only older men (not women) perpetrated homicide-suicide in later life (Cohen, 1998).

A few studies found more female perpetrators than male (Dunlop, 2000; Anetzberger, 1998). These studies included neglect, where women tend to exhibit higher rates of abuse than men (possibly because women provide more care than men). Pillemer (1988), using the Conflict Tactics Scale, also found women more likely to use physical violence than men. Unfortunately, the Conflict Tactics Scale does not differentiate between levels of physical violence. Throwing something across the room rates equally to choking a victim. The scale also does not take into account which party may be living in fear or have changed their lifestyle as a result of the abuse.

The NEAIS study (1998) identified that more than 1/3 of perpetrators are age 60 or older. These abusers are predominately spouse/partner abusers but may also include older adult children abusing their parents who are in their 80’s or 90’s. In addition, Phillips (2000) found that many older caregivers (age 55+) were being abused by their (older) care recipient.

LIMITATIONS OF STUDIES

Numerous limitations in the research on abuse in later life were found. In part because of the lack of financial resources, only a few studies have been large (more than 1,000 respondents) random sample studies (Lachs 1997a; Podnieks, 1992a; Pillemer, 1988). Even these large studies ultimately based their conclusions on relatively small numbers of abuse victims, ranging from 47 to 80. Only one of the random sample studies included cognitively impaired elders (achieved by interviewing other family members), but using the reports of proxies is considered unreliable (The Robert Wood Johnson Foundation, 2001).

All the other studies had serious sampling biases because they were based on elders who were using services of some sort and/or were known to adult protective services or domestic violence programs. This is problematic, because it is clear that many abused elders are isolated and do not come to the attention of professionals or seek help. With one exception (Otiniano, 1998), these studies also involved relatively small samples – 10 to 401, with the majority being under 100. Respecting the confidentiality and safety of victims creates problems with many scientific methods. Very few studies used control groups.
In addition, some elders deny that what they are experiencing is abuse (see, for example, Phillips, 2000), introducing another source of underreporting. Perhaps more importantly, studies have shown that elders’ definitions of abuse do not always correspond to professionals’ definitions, which may confound findings.

Comparing results across studies is practically impossible. These studies varied widely in: the types of abuse studied, the specific definitions of the types of abuse studied; whether abuse was self-reported or from agency records; the age of respondents (which ranged all the way down to 40); whether the target audience was predominately healthy elders or vulnerable adults; and whether only women or men and women were included.

POTENTIAL IMPLICATIONS

Given the number of studies identifying mental health or substance abuse problems among abusers, professionals in domestic violence/sexual assault, aging and adult protective services must work closely with providers in these systems. These services must include or be in addition to programs focusing on ending abusive behavior.

Professionals and community members require training to consider an adult child’s dependence (emotional, daily living or financial) as a potential red flag for abuse. Too often professionals look for the dependency of the victim as a red flag rather than the dependency of the potential abuser. Focusing questions on all parties’ financial dependency may help providers begin to identify other forms of abuse.

While the research identified men as the primary abusers of older people, a higher percentage of women were abusers than is seen in younger domestic violence. More services for women abusers, particularly those who neglect older people they provide care for, will need to be created.

Finally, services must be created to hold older abusers accountable and change their behavior to truly keep victims safe. Currently, batterers treatment programming is not designed for older batterers or adult children/grandchildren who are abusive. Like services tailored for older battered women, age-specific services may be needed to work with older perpetrators and adult children, other family members or caregivers who abuse elders.
